

## Exercise 4: Evaluation of the analysis

The analysis shows values only for comparison, no absolute risk results. I think that the analysis represents meaningful results for the Risk of cells, but only in comparison with other cells in this analysis/region. It cannot be compared to other regions, only if the same analysis will be done there.

The analysis is not complete, because the classes are often random. For example, the classified distance. There should be used pre-defined classes. Also, the weighting is not correct, because I used the value 1 for all criteria. There should be used a weighting which is backup by research.

That is the Risk for every cell.
